## **Abstract content**

We briefly summarize current experimental and theoretical results on the two important processes of the low energy hadron physics involving neutral pions: the Dalitz decay of  $\pi^0$  and the rare decay  $\pi^0 \to e^+e^-$ . As novel results we present the complete set of radiative corrections to the Dalitz decays  $\eta^{(\prime)} \to \ell^+\ell^-\gamma$  beyond the soft-photon approximation, i.e. over the whole range of the Dalitz plot and with no restrictions on the energy of a radiative photon. The corrections inevitably depend on the  $\eta^{(\prime)} \to \gamma^* \gamma^{(*)}$  transition form factors. For the singly virtual transition form factor appearing e.g. in the bremsstrahlung correction, recent dispersive calculations are used. For the one-photon-irreducible contribution at the one-loop level (for the doubly virtual form factor), we use a vector-meson-dominance-inspired model while taking into account the  $\eta$ - $\eta'$  mixing.
