# Ground-based research for radiation protection in space travel

Marco Durante

25.3.2022

FAIR seminars - Jagellonian Univeristy- Krakow

## EXPANDING HUMAN PRESENCE IN PARTNERSHIP

*CREATING ECONOMIC OPPORTUNITIES, ADVANCING TECHNOLOGIES, AND ENABLING DISCOVERY*

Now

Using the International Space Station

### Phase 0

Continue research and testing on ISS to solve exploration challenges. Evaluate potential for lunar resources. Develop standards.

2020s

Operating in the Lunar Vicinity (proving ground)

### Phase 1

Begin missions in cislunar space. Initiate next key deep space capability.

After 2030

Leaving the Earth-Moon System and Reaching Mars Orbit

### Phase 2

Complete next deep space capability and checkout.

The Global Exploration Roadmap

*Review*

# Galactic Cosmic Radiation

## GCR Charge Contributions

# PERSONAL DOSIMETRY

**Personal dosimetry:** Surveillance of the radiation exposure of astro – and cosmonauts (passive)

# Radiation dose during the travel to Mars and on the planet's surface measured by RAD on MSL

## RAD Instrument Overview

*RAD – The Radiation Assessment Detector for MSL*

RAD was selected for MSL to characterize the radiation environment (charged and neutral) on the surface of Mars. RAD consists of:

- Solid state detector telescope & CsI calorimeter for charged particles.
- Plastic scintillator w/ anti-coincidence logic to detect neutrons.
  - CsI detects  $\gamma$ -rays also, but RTG background is high.

- Mass = 1.56 kg
- Power = 4.2 W
- Volume = 10 x 12 x 20 cm<sup>3</sup>
- Field-of-View = 65 deg. (full angle)
- Geometry Factor = 1 cm<sup>2</sup> sr

Launch date: 26.11.2011

Landing date: 06.08.2012

# Dose summary for Mars & ISS

GCR dose in different mission scenarios based on the recent MSL measurements (Zeitlin et al., 2013; Hassler et al., 2014). Inspiration Mars is a 501 flyby mission. Mars sortie assumes a 30-days stay on the planet, and Mars base 500 days. Both those design reference missions (Tito et al., 2013) assume a 180 cruise to/from Mars.

	GCR dose rate (mGy/day)	GCR dose-equivalent rate (mSv/day)	Inspiration Mars (Sv)	Mars sortie (Sv)	Mars base (Sv)
MSL cruise (Zeitlin et al., 2013)	0.46	1.84	0.92	0.7	0.98
MSL on Mars (Hassler et al., 2014)	0.21	0.64			

**Table 2.** Summary of International Space Station (ISS) organ dose equivalents for solid cancer, leukemia and circulatory disease risk estimates for different solar cycle conditions for females (males).

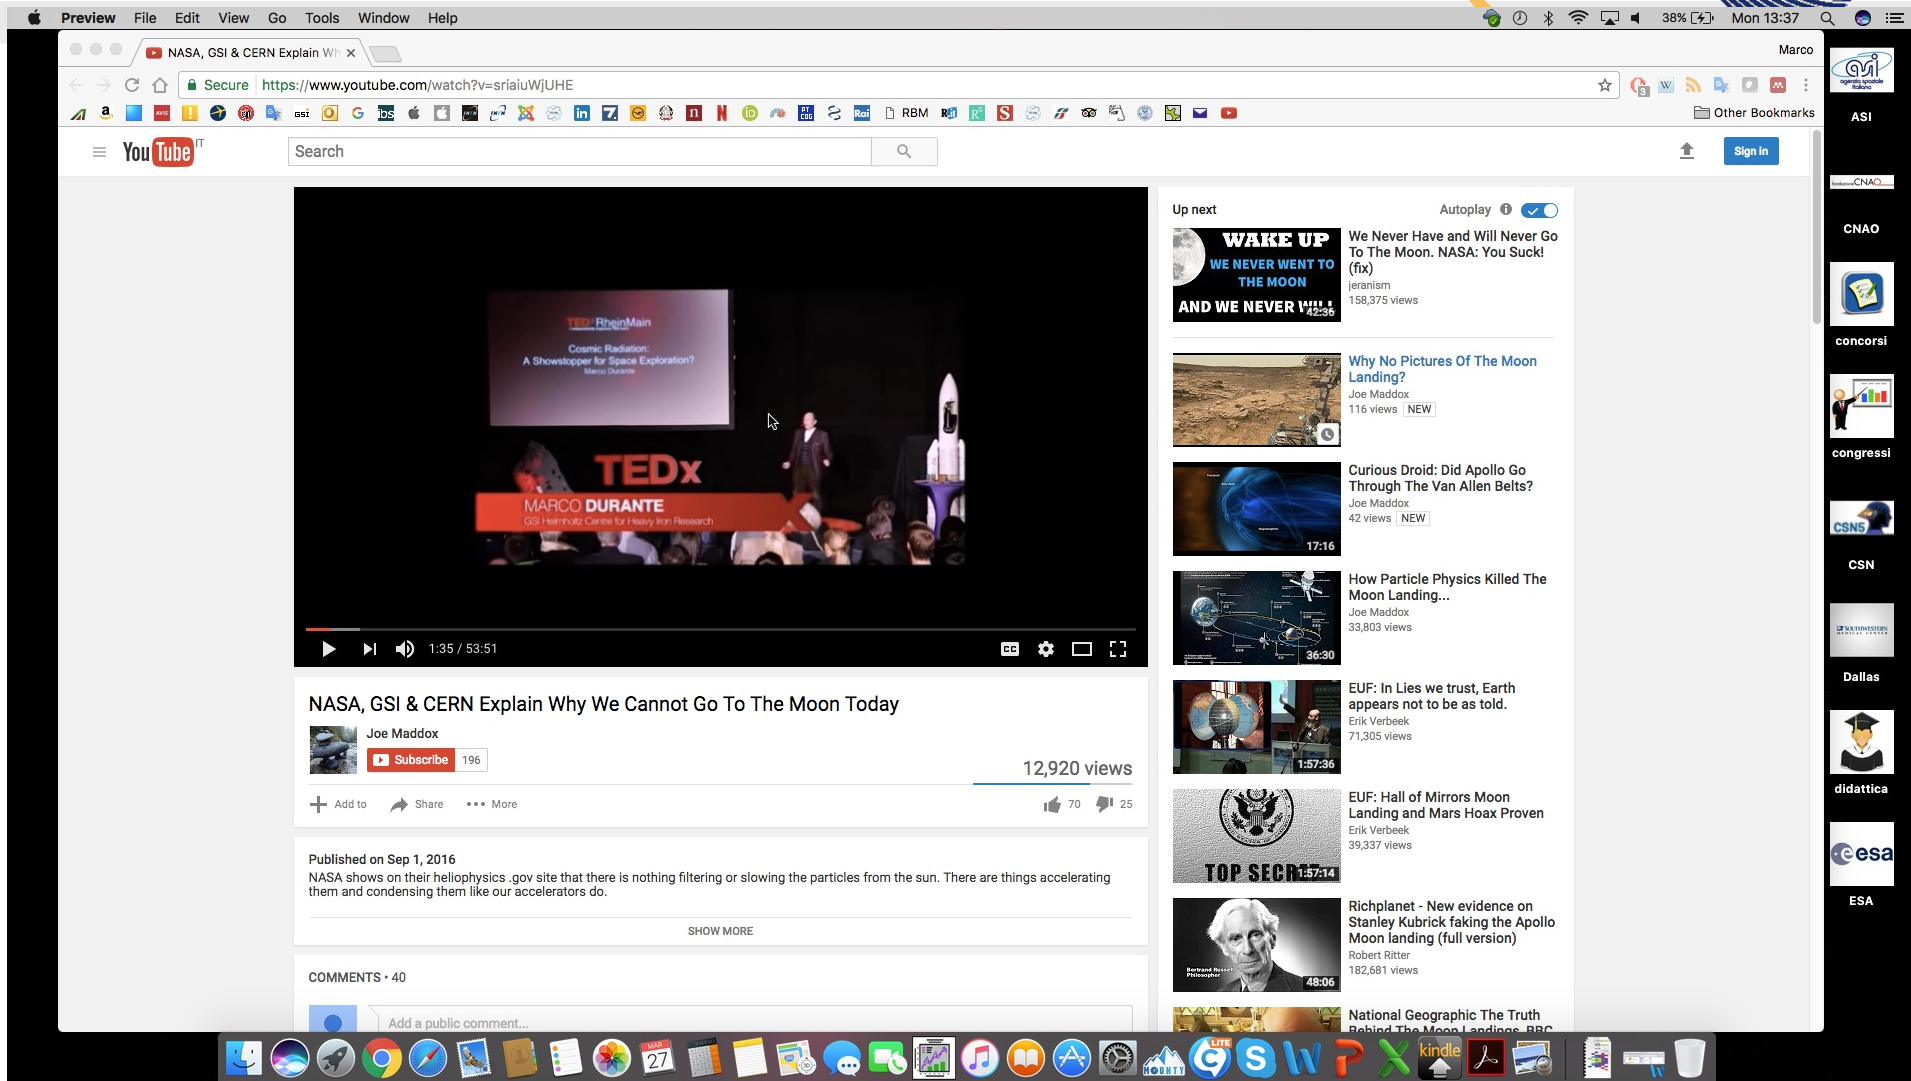

Missions	Solid Cancer, Sv	Leukemia, Sv	Circulatory Disease, Gy-Eq
1-Y Solar Min	0.187 (0.175)	0.109 (0.104)	0.132 (0.126)
1-Y Solar Med	0.146 (0.138)	0.084 (0.08)	0.10 (0.096)
1-Y Solar Max	0.10 (0.094)	0.054 (0.052)	0.072 (0.064)
1-Y Solar Min and 0.5-Y Solar Med	0.26 (0.244)	0.151 (0.144)	0.182 (0.174)
1-Y Solar Min, 0.5-Y Solar Med, and 0.5-Y Solar Max	0.31 (0.291)	0.178 (0.171)	0.215 (0.205)

Predictions are for single or multiple ISS missions. Solar cycle conditions considered are average solar minimum (Solar Min), average solar maximum (Solar Max), or median solar cycle (Solar Med), with solar modulation parameters for these conditions described in [2].

Space travelers are exposed to unique forms of ionizing radiation that pose potentially serious health hazards. Prior analyses have attempted to quantify excess mortality risk for astronauts exposed to space radiation, but low statistical power has frustrated inferences. If exposure to deep space radiation were causally linked to deaths due to two particular causes, e.g., cancer and cardiovascular disease, then those cause-specific deaths would not be statistically independent. In this case, a Kaplan-Meier survival curve for a specific cause that treats deaths due to competing causes as uninformative censored events would result in biased estimates of survival probabilities. Here we look for evidence of a deleterious effect of historical exposure to space radiation by assessing whether or not there is evidence for such bias in Kaplan-Meier estimates of survival probabilities for cardiovascular disease and cancer. Evidence of such bias may implicate space radiation as a common causal link to these two disease processes. An absence of such evidence would be evidence that no such common causal link to radiation exposure during space travel exists. We found that survival estimates from the Kaplan-Meier curves were largely congruent with those of competing risk methods, suggesting that if ionizing radiation is impacting the risk of death due to cancer and cardiovascular disease, the effect is not dramatic.

REID is larger for females than for males and decreasing with age. 30% difference@30 years

## New NASA radiation standards for astronauts seen as leveling field for women

By Anil Oza | Jun. 29, 2021, 10:35 AM

A blue-ribbon panel has endorsed NASA's plans to revise its standard for exposing astronauts to radiation in a way that would allow women to spend more time in space.

A report by the U.S. National Academies of Sciences, Engineering, and Medicine released on 24 June encourages NASA to proceed with its plans to adopt a new standard that limits all astronauts to 600 millisieverts of radiation

## Blue team: research should be in space

- Mixed radiation field: protons+HZE+photons+neutrons
- Energies from few eV to TeV
- High fluence of protons (low dose rate) + low fluence HZE (high local dose)
- Exposure under strong stress conditions: microgravity, immune system depression, hypoxia
- Evidence that the space environment can affect organ functions, tissue growth, cellular metabolism and gene expression
- Space environment cannot be fully reproduced on Earth
- Space agencies think that space science = space flight

## Red team: research should be on Earth

- Experiments in space are very expensive
- Many hindrances and boundary conditions, need custom hardware, very little crew time available, sometimes no sample return
- Experiments conditions are scarcely under control
- It is almost impossible to repeat the experiments
- Dose rate in space is very low (<1 mSv/day), but spaceflight related stress is very high: very low signal/noise ratio
- Accelerators can reproduce many aspects of the radiation environment

## → SPACE RISKS

### Radiation

#### Study it

Five European accelerators in Europe run simulations for physics research.

#### Set limits

How much can you take? Radiation risk models with dose limits for missions to the Moon and Mars.

#### Measure it

European dosimeters monitor radiation on the International Space Station and on NASA's Orion spacecraft.

#### Protect from it

Space agencies invest in radiation vests for the crew and radiation-hardened components for spacecraft.

#### Hazards for equipment

Space radiation remains one of the leading causes of satellite anomalies. This **invisible threat** can quickly degrade the circuits with serious consequences – it can even lead to the end of a space mission.

#### Sources of radiation

**Galactic cosmic rays**  
Radiation background from beyond the Solar System modulated by the solar cycle. Cosmic radiation is **always there**, and it could lead to higher risk of cancer.

#### Solar particle event

The Sun delivers a high amount of radiation in a **short period** of time. This virulent burst of high-energy particles is unpredictable.

# ESA-FAIR Summer School in Darmstadt

[www.gsi.de/esa-fair-summer-school.htm](http://www.gsi.de/esa-fair-summer-school.htm)

- Space radiation is the main health risk for humans in space and a potential showstopper for exploration
  - High uncertainty on radiation risk caused by the radiation quality difference compared to Earth
  - Lack of reliable countermeasures, due to the high energy of the cosmic radiation
  - Need for more research at high-energy particle accelerators
  - Need for common risk models and dose limits for international exploratory-class missions

Thanks you very much!
